Render Movie

# factor of reusability → DRY principle

↓  
Don't Repeat yourself

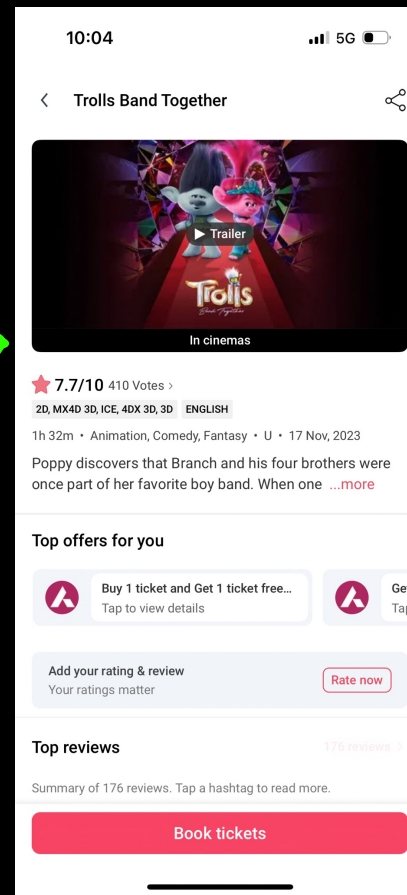

Dwa → donot need to know algo

needs to know what data to pass

Block Box

this block box has algo to render the UI

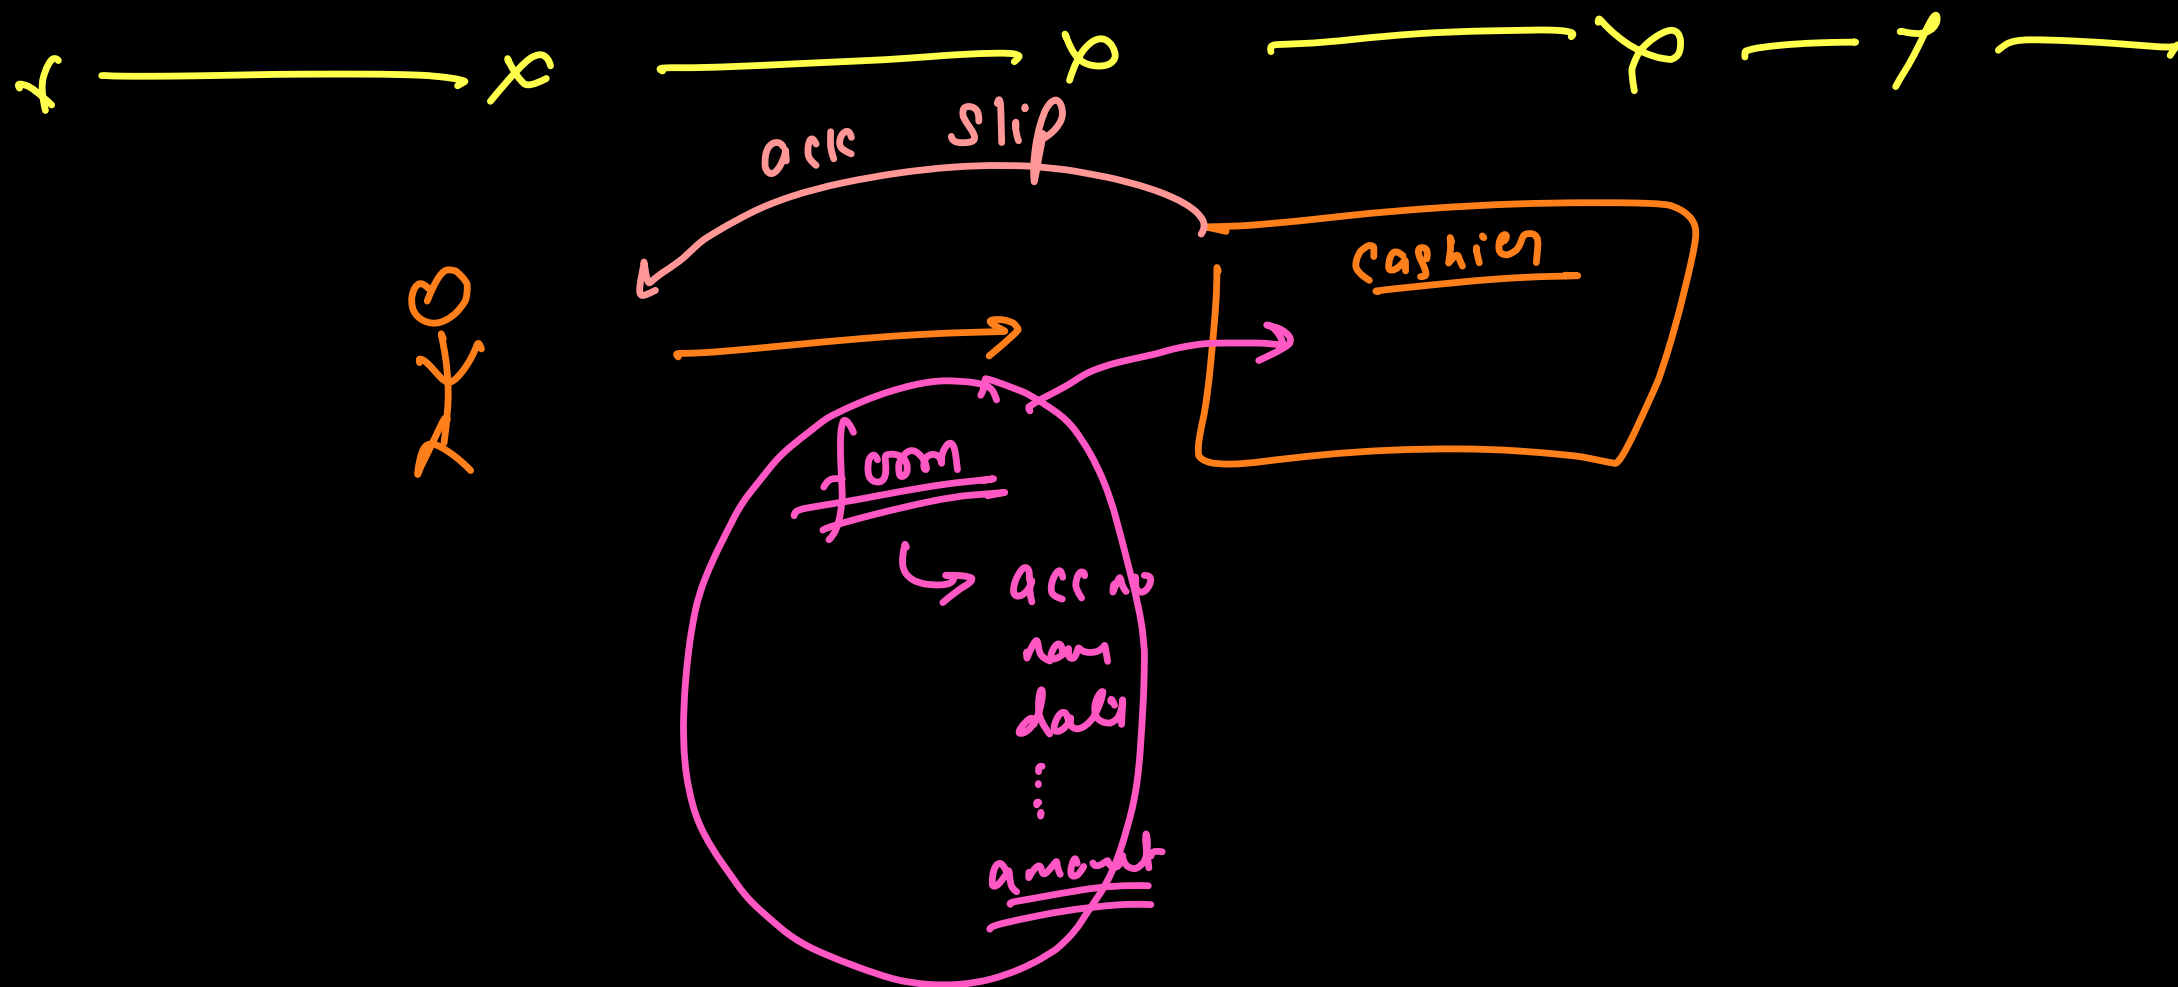

Functions

$y = f(x)$  input  $f \rightarrow$  sgort

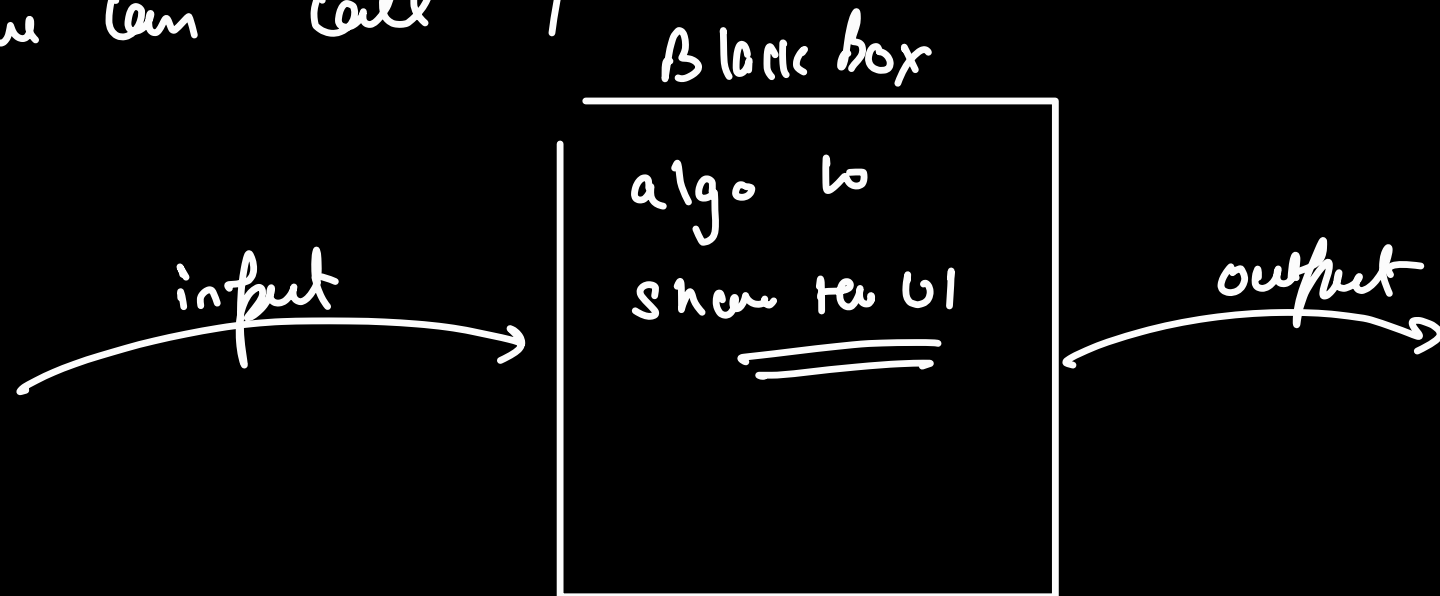

output

# Functions

- most of the prog lang has got concept of func<sup>n</sup>.
- func<sup>n</sup> help us to implement DRY principle.
- functions help us to wrap a piece of code together and reuse it wherever reqd.
- we can call func<sup>n</sup> to execute the logic they're wrapped

→ Some func<sup>n</sup> might not need any input e.g.

Q2 how to code it ?2

keyword  
function name Of The function (input non mandatory p1, p2, p3...) {

====  
==== logic / body  
====  
=====

12  
return output; }

keyword

In JS the return statement is also not mandatory. If you don't write a return statement, the func<sup>n</sup> automatically returns undefined.

```
console.log("Sanket");
```

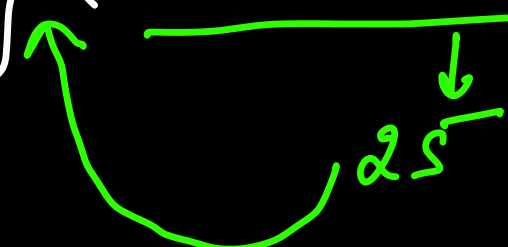

↳ black box

# How to call a func<sup>n</sup> ??

result = nameOfTheFunction ( input )

↖  
return ofp is stored  
in the variable

`console.log( calculateSquare(s) )`

$f(g(x))$

→ a lot of times you will see people doing  
`console.log` inside the func<sup>n</sup> instead of  
returning a value.

sign in → if ( premiumMember() ) {

} else {

→

}

you can give  
multiple parameters  
comma separated

## Arguments & Parameters To a func<sup>n</sup>

function    name Of The function ( p1, p2, p3... ) {  
    \_\_\_\_\_  
    \_\_\_\_\_  
    \_\_\_\_\_  
    \_\_\_\_\_  
    return    output;  
}

logic / body

parameters

func<sup>n</sup> definition

when we define a function, we define the input values,  
that the func<sup>n</sup> expects. These are not actual values  
instead just a placeholder that will later store  
actual values when func<sup>n</sup> is called.

calculate Square (9); ← func call  
    ↳ this is an actual i/p we are  
    passing to the func.  
this is an argument.

Q ⇒ write a function to calculate sum of some numbers passed as an argument. Return the sum as output.

how to handle any no. of args.

addNumbers (); // 0

addNumbers (2, 3); // 5

addNumbers (1, 1, 1, 1, 1, 1); // 6

↓

we don't know how many arguments will come up.

How to decide how many parameters to write in

the function logic ! ? !

→ variable arguments

- arguments keyword
- spread operator (...) → hold

arguments gives us access to a special object that  
supports array like syntax, and can be used to  
fetch all variable args.
